

Chapter 1

Example problem: The spatially-adaptive solution of the azimuthally Fourier-decomposed 3D Helmholtz equation

In this document we discuss the spatially-adaptive finite-element-based solution of the 3D Helmholtz equation in cylindrical polar coordinates, using a Fourier-decomposition of the solution in the azimuthal direction.

The driver code is very similar to the one discussed in [another tutorial](#) – the main purpose of the current tutorial is to demonstrate the use of spatial adaptivity on unstructured meshes.

1.1 A specific example

We will solve the azimuthally Fourier-decomposed Helmholtz equation

$$\nabla^2 u_N(r, z) + \left(k^2 - \frac{N^2}{r^2} \right) u_N(r, z) = 0, \quad (1)$$

where N is the azimuthal wavenumber, in the finite domain $1 < \sqrt{r^2 + z^2} < 3$. We impose the Sommerfeld radiation condition at the outer boundary of the computational domain at $\sqrt{r^2 + z^2} = 3$, using a Dirichlet-to- \leftrightarrow Neumann mapping, and apply flux boundary condition on the surface of the unit-sphere (where $\sqrt{r^2 + z^2} = 1$) such that the exact solution is given by

$$u_N(r, z) = u_N^{[exact]}(r, z) = \sum_{l=N}^{N_{\text{terms}}} h_l^{(1)}(k\sqrt{r^2 + z^2}) P_l^N \left(\frac{z}{\sqrt{r^2 + z^2}} \right).$$

This solution corresponds to the superposition of several outgoing waves that emerge from the unit sphere. The two plots below show a comparison between the exact and computed solutions for $N_{\text{terms}} = 6$, a Fourier wavenumber of $N = 1$, and a (squared) Helmholtz wavenumber of $k^2 = 10$.

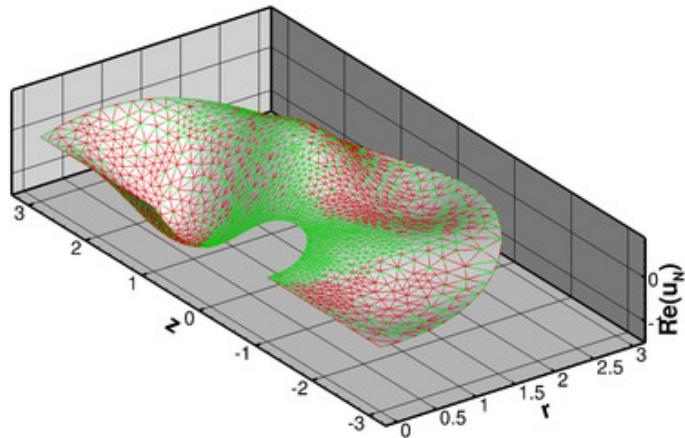

Figure 1.1 Plot of the exact (green) and computed (red) real parts of the solution of the Fourier-decomposed Helmholtz equation for $N=1$ and a wavenumber of $k^2 = 10$.

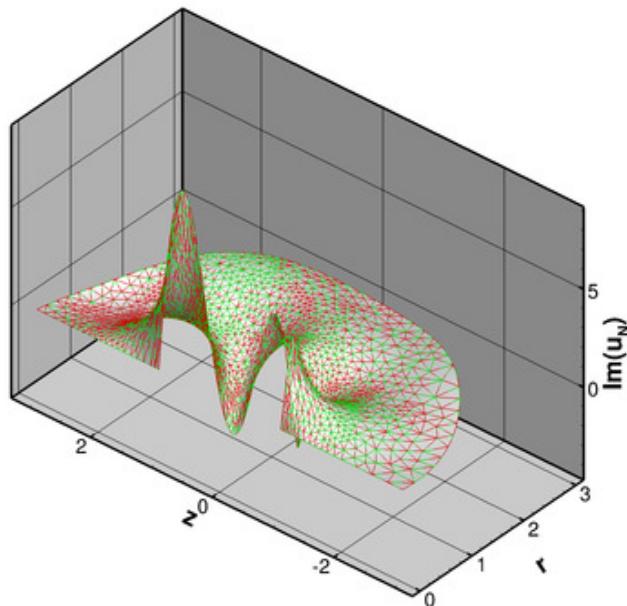

Figure 1.2 Plot of the exact (green) and computed (red) imaginary parts of the solution of the Fourier-decomposed Helmholtz equation for $N=1$ and a wavenumber of $k^2 = 10$.

1.2 The numerical solution

The driver code for this problem is very similar to the one discussed in [another tutorial](#).
Running `sdiff` on the driver codes

```
demo_drivers/fourier_decomposed_helmholtz/sphere_scattering/sphere_<br/>scattering.cc
```

and

```
demo_drivers/fourier_decomposed_helmholtz/sphere_scattering/unstructured_<-->  
sphere_scattering.cc
```

shows the main differences required to discretise the computational domain with an adaptive, unstructured mesh:

- The provision of the functions `actions_before/after_adapt()` to detach/re-attach the FaceElements that are used to enforce the Neumann boundary conditions before and after every spatial adaptation, and to pass the physical parameters to the newly created bulk elements.
 - The generation of an unstructured mesh whose curvilinear boundaries are represented by GeomObjects – this ensures that the domain boundaries become increasingly well resolved under mesh refinement.

That's all!

1.3 Code listing

Here's a listing of the complete driver code:

```

double K=3.0*MathematicalConstants::Pi;

// Imaginary unit
std::complex<double> I(0.0,1.0);

// Exact solution as a Vector of size 2, containing real and imag parts
void get_exact_u(const Vector<double>& x, Vector<double>& u)
{
    // Switch to spherical coordinates
    double R=sqrt(x[0]*x[0]+x[1]*x[1]);

    double theta;
    theta=atan2(x[0],x[1]);

    // Argument for Bessel/Hankel functions
    double kr = K*R;

    // Need half-order Bessel functions
    double bessel_offset=0.5;

    // Evaluate Bessel/Hankel functions
    Vector<double> jv(N_terms);
    Vector<double> yv(N_terms);
    Vector<double> djv(N_terms);
    Vector<double> dyv(N_terms);
    double order_max_in=double(N_terms-1)+bessel_offset;
    double order_max_out=0;

    // This function returns vectors containing
    // J_k(x), Y_k(x) and their derivatives
    // up to k=order_max, with k increasing in
    // integer increments starting with smallest
    // positive value. So, e.g. for order_max=3.5
    // jv[0] contains J_{1/2}(x),
    // jv[1] contains J_{3/2}(x),
    // jv[2] contains J_{5/2}(x),
    // jv[3] contains J_{7/2}(x).
    CRBond_Bessel::bessjyv(order_max_in,
                           kr,
                           order_max_out,
                           &jv[0],&yv[0],
                           &djv[0],&dyv[0]);

    // Assemble exact solution (actually no need to add terms
    // below i=N_fourier as Legendre polynomial would be zero anyway)
    complex<double> u_ex(0.0,0.0);
    for(unsigned i=0;i<N_terms;i++)
